

UNITED STATES PATENT AND TRADEMARK OFFICE

I, Charles Edward SITCH BA,

Acting Managing Director of RWS Group Ltd UK Translation Division, of Europa House,
Marsham Way, Gerrards Cross, Buckinghamshire, England declare;

1. That I am a citizen of the United Kingdom of Great Britain and Northern Ireland.
2. That the translator responsible for the attached translation is well acquainted with the German and English languages.
3. That the attached is, to the best of RWS Group Ltd knowledge and belief, a true translation into the English language of the accompanying copy of the specification filed with the application for a patent in Germany on 13 December 2002 under the number 102 58 669.1 and the official certificate attached hereto.
4. That I believe that all statements made herein of my own knowledge are true and that all statements made on information and belief are true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the patent application in the United States of America or any patent issuing thereon.

For and on behalf of RWS Group Ltd

The 13th day of March 2007

FEDERAL REPUBLIC OF GERMANY

[Eagle crest]

**Priority Certificate
for the filing of a Patent Application**

File Reference: 102 58 669.1

Filing date: 13 December 2002

Applicant/Proprietor: BASF Aktiengesellschaft, Ludwigshafen/DE

Title: Method for the production of benzophenones

IPC: C 07 C 45/46

The attached documents are a correct and accurate reproduction of the original submission for this Application.

Munich, 7 November 2003

German Patent and Trademark Office

The President

[Seal of the German Patent
and Trademark Office]

Schmidt C.

We claim:

1. A process for preparing benzophenones of the formula I,

where X may be chlorine, hydroxyl, methoxy or C₁-C₆-alkylcarbonyloxy, and Y may be chlorine or bromine, by reacting an acid chloride of the formula II

where X and Y are as defined above with 3,4,5-trimethoxytoluene, which comprises carrying out the reaction in the presence of

- a) a diluent selected from the group of chlorobenzene, benzotrifluoride and nitrobenzene and
- b) from 0.01 to 0.2 mol% of an iron catalyst, based on the acid chloride,
- c) at a temperature between 60°C and the boiling point of the particular diluent.
2. A process as claimed in claim 1, wherein the diluent used is chlorobenzene.
3. A process as claimed in claim 1 or 2, wherein 3,4,5-trimethoxytoluene is initially charged, optionally in the particular diluent, and the acid chloride together with the iron catalyst is metered in, optionally in the particular diluent.
4. A process as claimed in any of claims 1 to 3, wherein the hydrochloric acid forming in the reaction is removed from the reaction mixture by stripping using an inert gas stream.

2

5. A process as claimed in any of claims 1 to 4, wherein the diluent is distilled off toward the end or during the course of the reaction, and the remaining product melt is crystallized in a C₁-C₆-alcohol.

5

6. A process as claimed in any of claims 1 to 5, wherein the acid chloride of the formula II is prepared by reacting an acid of the formula III

10

III

15

where X and Y are each as defined above with thionyl chloride or phosgene, optionally in the presence of dimethylformamide, in the same diluent which is also used in the subsequent Friedel-Crafts stage.

20

7. A process as claimed in claim 6, wherein, after formation of the acid chloride II, at least a portion of the diluent is distilled off with excess thionyl chloride and recycled into the process.

25

8. A process as claimed in claim 6, wherein the acid of the formula IIIa

30

IIIa

35

is prepared by brominating the compound IV

40

IV

with elemental bromine in the same diluent which is also used in the two subsequent stages.

9. A process as claimed in claim 8, wherein at least a portion of the diluent and excess bromine is distilled off at the end of the bromination and recycled into the process.

Method for the production of benzophenones

A process for preparing benzophenones of the formula I,

5

10

where X may be chlorine, hydroxyl, methoxy or C₁-C₆-alkylcarbonyloxy, and Y may be chlorine or bromine, by reacting an acid chloride of the formula II

15

20

where X and Y are as defined above with 3,4,5-trimethoxytoluene, which comprises carrying out the reaction in the presence of

- 25 a) a diluent selected from the group of: chlorobenzene, benzotrifluoride and nitrobenzene and
- b) from 0.01 to 0.2 mol% of an iron catalyst, based on the acid chloride,
- 30 c) at a temperature between 60°C and the boiling point of the particular diluent.

The benzophenones of the formula I are disclosed by EP-A 897 904.

- 35 In this case, the Friedel-Crafts acylation is carried out using stoichiometric amounts of aluminum chloride or phosphorus pentoxide. The diluents used were low boilers such as dichloromethane or benzene. The technical realization of this procedure leads to numerous problems. Particular disadvantages
- 40 are the aqueous workup and the inevitable occurrence of large amounts of aluminum- or phosphorus-containing wastewater.

- WO 01/51440 describes a process for preparing benzophenones I which works in the presence of iron(III) chloride and
- 45 considerable amounts of graphite. The diluent used is 1,2-dichloroethane. The yield of isolated benzophenone is only

2

approx. 72%. The removal of the graphite also entails an additional filtration step.

- It is an object of the present invention to provide an
- 5 economically viable and selective process for preparing the benzophenones I, which works with catalytic amounts of a Friedel-Crafts catalyst and at the same time delivers high space-time yields.
- 10 It has now been found that, surprisingly, the disadvantages present in the prior art can be avoided when the reaction is carried out in the presence of
- a) a diluent selected from the group of: chlorobenzene,
15 benzotrifluoride and nitrobenzene and
 - b) from 0.01 to 0.2 mol% of an iron catalyst, based on the acid chloride,
 - 20 c) at a temperature between 60°C and the boiling point of the particular diluent.

The iron catalyst used is generally finely ground iron powder or iron(III) salts. Preference is given to iron(III) oxide and
25 particular preference to iron(III) chloride.

Useful diluents are high-boiling aromatic hydrocarbons which are inert under the reaction conditions: chlorobenzene, benzotrifluoride and nitrobenzene. Particular preference is given
30 to chlorobenzene.

The use of a relatively high-boiling diluent also has the advantage that the hydrochloric acid forming in the reaction can be removed using an inert gas stream which is preferably passed
35 through the reaction mixture, without resulting in significant diluent losses. It is evident from the preparative examples that the reaction times can be drastically reduced by the inert gas stripping. This allows reaction times of less than 10 hours to be realized even with very low catalyst amounts, for example less
40 than 0.1 mol%, without having to accept relatively large yield losses. Useful inert gases are noble gases such as argon, air and preferably nitrogen. The inert gas stream is preferably passed through the reaction mixture. It is advantageous, for example, to achieve a very fine distribution of the gas particles in the
45 reaction mixture. This can be effected, for example, by means of a jet or of a sparging ring, and these means are advantageously mounted below the stirrer. The amount of gas passed through the

3

reaction mixture depends in particular on the batch size. Up to 5 l/h of inert gas are introduced per mole of acid chloride.

The use of the diluent according to the invention also has the
5 advantage that the Friedel-Crafts acylation can be carried out at relatively high temperatures, which again allow the reaction times to be reduced. In general, operation is effected within the temperature range of from 60°C to the boiling point of the diluent, preferably within the temperature range of from 80 to
10 150°C.

The iron catalyst is used in a molar ratio of from 0.01 to 0.2 mol%, based on the acid chloride. Preference is given to using from 0.03 to 0.1 mol% of the catalyst.

15 The 3,4,5-trimethoxytoluene is also generally used in a molar ratio of from 1 to 3, based on the acid chloride. Preference is given to using a slight excess of from 1.05 to 1.4 molar equivalents of 3,4,5-trimethoxytoluene.

20 In a preferred embodiment of the process, the 3,4,5-trimethoxytoluene is initially charged, optionally in the diluent, and the iron catalyst and the acid chloride are metered in, optionally in the diluent, within from 0.5 to 20 hours,
25 preferably from 4 to 6 hours, depending on the selected reaction temperature. The iron catalyst is preferably metered in dissolved in the acid chloride.

The reverse procedure (metering in of 3,4,5-trimethoxytoluene) as
30 a one-pot variant has apparatus advantages when acid chloride has already been prepared in the same reaction vessel. As is evident from table 1, this procedure leads to a somewhat lower selectivity and yield in an otherwise identical procedure.

35 On completion of metering in, the reaction mixture is generally stirred for up to a further 20 hours and preferably from 2 to 4 hours. The continued stirring time can generally be shortened when the solvent and any excess 3,4,5-trimethoxytoluene are distillatively removed at the end of the Friedel-Crafts
40 acylation. The distillation can be begun when only a partial conversion has been achieved. The distillation time can be used to complete the conversion.

The distillative removal of the diluent is the preferred workup
45 variant. The distillation residue remaining in the reaction vessel is a melt of the desired benzophenone which can be crystallized using a C₁-C₆-alcohol, preferably methanol. It may

often be advantageous to add small amounts of water to the alcohol, in order to completely dissolve the iron salts.

The process according to the invention is suitable in particular for preparing 5-bromo-2',6-dimethyl-2,4',5',6'-tetramethoxybenzophenone. The process according to the invention can also be used to prepare, for example, 2,5-dichloro-2',6-dimethyl-4',5',6'-trimethoxybenzophenone, 5-chloro-2',6-dimethyl-2-hydroxy-4',5',6'-trimethoxybenzophenone or 5-bromo-2',6-dimethyl-2-hydroxy-4',5',6'-trimethoxybenzophenone. In the case of the two latter compounds, it may be advisable to protect the free hydroxyl group in the 2-position in the form of a C₁-C₆-alkyl-carboxyloxy group and to detach it again after the end of the Friedel-Crafts acylation.

The process according to the invention also has the advantage that the preparation of the acid chloride II and also the bromination to the acid IIIa may be carried out in the same diluent as the Friedel-Crafts acylation. As shown in scheme 1 using the example of the preparation of 5-bromo-2',6-dimethyl-2,4',5',6'-tetramethoxybenzophenone (I'), (i) the bromination of 2-methoxy-6-methylbenzoic acid IV' to 5-bromo-2-methoxy-6-methylbenzoic acid IIIa', (ii) the subsequent conversion to the acid chloride II' and finally (iii) the Friedel-Crafts acylation to benzophenone I' can all be carried out in chlorobenzene.

5

Depending on the metering sequence in the Friedel-Crafts stage, all three reaction steps can therefore be combined in a one-pot variant.

- 5 The relatively high boiling points of the diluent in the process according to the invention also allow the starting materials (bromine in the bromination step, thionyl chloride (phosgene) in the acid chloride stage and 3,4,5-trimethoxytoluene in the Friedel-Crafts stage, each of which is preferably used in excess) to be distillatively removed and recycled back into the particular process (i to iii). When benzotrichloride or chlorobenzene are used as diluents, the boiling point differences allow a diluent to be obtained by distillation in the Friedel-Crafts stage (iii) which is free of 3,4,5-trimethoxytoluene and can therefore be recycled directly into the bromination stage (i).

- The formation of the acid chloride (stage ii) can be effected as described specifically in the literature. The chlorinating agent used is generally thionyl chloride or phosgene. The reaction temperature is typically from room temperature to 80°C.

- The bromination (stage i) may be carried out as described in the literature. The reaction can either be carried out in the presence of, although preferably without, acid catalysis. The reaction temperature is generally from 0 to 80°C.

Process examples

- 30 Examples 1 to 7

General process procedure for preparing 5-bromo-2',6-dimethyl-2,4',5',6'-tetramethoxybenzophenone (I') starting from 5-bromo-2-methoxy-6-methylbenzoyl chloride (II')

- 35 A solution of 1047 g (3.973 mol) of 5-bromo-2-methoxy-6-methylbenzoyl chloride in 1715 g of chlorobenzene was admixed with 0.72 g (0.0044 mol) (examples 1 to 4 and 7) or 0.36 g (0.0022 mol) (example 5) or 0.18 g (0.0011 mol) (example 6) of anhydrous iron(III) chloride and metered into a solution of 868.7 g (4.768 mol) of 3,4,5-trimethoxytoluene in 467.8 g of chlorobenzene at the reaction temperature stated in the table over 4 h. Subsequently, the reaction mixture was stirred at the reaction temperature for a further 2 h. To remove the HCl formed, a constant nitrogen stream was passed through the reaction mixture during the metering and continued stirring time (the particular flow rate may be taken from the table). Subsequently,

6

the chlorobenzene was distilled off at 80 mbar and temperatures of 80-105°C. Purity and yield of the crude product melt were determined by means of quantitative HPLC before crystallization (see table for results).

5

To crystallize the 5-bromo-2',6-dimethyl-2,4',5',6'-tetramethoxybenzophenone (I'), 4900 g of methanol were initially charged at 50°C and the melt at 105°C was introduced. The crystallization was effected by cooling by means of a temperature ramp down to -5°C.

10 The title compound was isolated by centrifugation, washed with methanol on the centrifuge and dried.

15	Experiment	Mole percent of FeCl ₃	N ₂ flow rate	Reaction temperature	Conversion after 6 h	Selectivity	Yield after dist.
	1	0.11	10 l/h	80°C	76.7%	99.3%	97.4%
	2	0.11	10 l/h	100°C	90.4%	99.3%	97.5%
	3	0.11	5 l/h	120°C	96.0%	98.9%	98.3%
20	4	0.11	10 l/h	145°C	100.0%	97.8%	97.5%
	5	0.06	10 l/h	145°C	99.5%	99.4%	99.0%
	6	0.03	10 l/h	145°C	99.3%	99.2%	98.9%

25	reverse ordering of metering						
	7	0.11	10 l/h	145°C	100.0%	89.4%	89.4%

Example 8

30

Preparation of 5-bromo-2',6-dimethyl-2,4',5',6'-tetramethoxybenzophenone (I') starting from 2-methoxy-6-methylbenzoic acid (IV')

35 (i) Preparation of 5-bromo-2-methoxy-6-methylbenzoic acid (IIIIa')

700 g (4.212 mol) of 2-methoxy-6-methylbenzoic acid (IV') were suspended in 2343.5 g of chlorobenzene, and 707.2 g (4.423 mol) of elemental bromine were subsequently added dropwise within 3 h at a constant internal temperature of 15°C. Afterwards, the mixture was stirred at 35°C for 2 h. Subsequently, 628.7 g of chlorobenzene were distilled off at an internal temperature of 77-82°C and 200 mbar, and the excess bromine and HBr were likewise removed from the reaction vessel. After analysis of the bromine content, the brominous chlorobenzene distillate could be reused

45

7

in the next batch without any discharge. The amount of bromine to be used there could be correspondingly reduced.

The composition of the crude mixture was determined by

- 5 quantitative HPLC. 980.5 g (4.0 mol = 95% yield) of a suspension of IIIa' in chlorobenzene were obtained. The selectivity of the bromination is high. The ratio of 5-bromo to 3-bromo compound is >500:1.

10 (ii) Preparation of 5-bromo-2-methoxy-6-methylbenzoyl chloride (II')

- The suspension obtained under (i) was diluted by adding 754.8 g of chlorobenzene and cooled to a temperature of 50°C. 0.95 g
15 (0.013 mol) of dimethylformamide was then added, and 528.8 g (4.445 mol) of thionyl chloride were subsequently metered in at an internal temperature of 50°C within 1.5 h. Finally, stirring was continued at 50°C for a further 1.5 h. Afterwards, 754.8 g of chlorobenzene were distilled off at an internal temperature of
20 83-90°C at 200 mbar, and excess thionyl chloride and residual hydrochloric acid and sulfur dioxide were also removed from the reaction mixture. After analyzing the thionyl chloride content, the thionyl chloride-containing chlorobenzene distillate could be reused in the next batch without any discharge. The amount of
25 thionyl chloride to be used there could be correspondingly reduced.

- The product of value content of the distillation residue was determined by means of quantitative HPLC. 1047 g (3.973 mol =
30 99.5% yield) of 5-bromo-2-methoxy-6-methylbenzoyl chloride were obtained as a solution in chlorobenzene.

iii) Preparation of
5-bromo-2',6-dimethyl-2,4',5',6'-tetramethoxybenzophenone (I')

- 35 The preparation was effected in a similar manner to examples 1 to 7, likewise in chlorobenzene. The yield and purity of the products formed may be taken from the table.

40

45

Method for the production of benzophenones

Abstract

5

A process for preparing benzophenones of the formula I,

10

I

15 where X may be chlorine, hydroxyl, methoxy or C₁-C₆-alkylcarbonyloxy, and Y may be chlorine or bromine, by reacting an acid chloride of the formula II

20

II

25 where X and Y are as defined above with 3,4,5-trimethoxytoluene, which comprises carrying out the reaction in the presence of

a) a diluent selected from the group of: chlorobenzene, benzotrifluoride and nitrobenzene and

30

b) from 0.01 to 0.2 mol% of an iron catalyst, based on the acid chloride,

c) at a temperature between 60°C and the boiling point of the particular diluent.
